# About

DVRPC's IPD analysis identifies populations of interest under Title VI of the Civil Rights Act and the Executive Order on Environmental Justice (#12898) using 2013-2017 American Community Survey (ACS) five-year estimates from the U.S. Census Bureau. IPD analysis assists both DVRPC and outside organizations in equity work by identifying populations of interest, including Youth, Older Adults, Female, Racial Minority, Ethnic Minority, Foreign-Born, Limited English Proficiency, Disabled, and Low-Income populations at the census tract level in DVRPC's nine-county region.

There are many ways of identifying these populations of interest. This document discusses DVRPC's process, which is automated in an R script.

## Project file structure

The easiest way to run this script is to download the entire repository from Github (link). The script uses relative file paths but it looks for subfolders in the following structure:

Insert file structure here.

Script components (to be fixed later)

- 1. Setup
- 2. Variance Replicate Table Download and Processing
- 3. ACS Estimates Download
- 4. Calculations
- 5. Cleaning
- 6. Summary Tables
- 7. Export

#### Script outputs

- 1. ipd.csv, the primary output
  - Estimated count of residents for each indicator (CntEst)
  - Margin of error (MOE) associated with the count (CntMOE)
  - Estimated percentage of residents for each indicator (PctEst)
  - MOE associated with the percentage (PctMOE)
  - Percentile as compared to the study area, ranging from 0 to 1 (Pctile)
  - IPD score of the percentage, ranging from 0 to 4 (Score)
  - Text explanation and equivalent of the IPD score (Class)
  - Overall IPD score (IPD\_Score)
  - Universes and their MOEs used in analysis
- 2. counts\_by\_indicator.csv, a summary of the number of tracts that recieve each IPD score (0-4) for each indicator
- 3. breaks\_by\_indicator.csv, a summary of the break values used for each indicator
- 4. export\_summary.csv, the minimum, median, mean, standard deviation, and maximum value of each indicator
- 5. mean\_by\_county.csv, a summary of each indicator aggregated to the county level for DVRPC's nine-county region

# 1. Setup

## 1a. Dependencies

Packages required to run this script. If you don't have the packages, you'll get the warning Error in library (<name of package>): there is no package called '<name of package>', in which case you'll need to install the package before proceeding.

library(plyr); library(tidycensus); library(tidyverse); library(here); library(summarytools)

#### 1b. Fields

The base information we need for IPD analysis are universes, counts, and percentages for nine indicators at the census tract level. For each indicator, the table below shows the indicator name, its abbreviation used in the script, its universe, its count, and its percentage field if applicable. Because the schemata of ACS tables can change with every update, these field names are applicable *only* to 2013-2017 ACS 5-Year Estimates.

Some percentage fields are empty. This is okay: we will compute the percentages when they are not directly available from the ACS.

Note that variable B02001\_002 ("Estimate; Total: - White alone") is listed as the count for Racial Minority. This is a mathematical shortcut: otherwise, we would need to add several subfields to compute the same estimate. The desired count is B02001\_001 (Universe) - B02001\_002 ("Estimate; Total: - White alone"). The subtraction is computed after download, making a correct estimate and an incorrect MOE. The correct MOE for the count, as calculated in Section 2, will be appended later in Section 3.

Indicator	Abbreviation	Universe	Count	Percentage
Youth	Y	B03002_001	B09001_001	N/A
Older Adults	OA	S0101_C01_001	S0101_C01_030	S0101_C02_030
Female	$\mathbf{F}$	S0101_C01_001	S0101_C05_001	$DP05\_0003PE$
Racial Minority	RM	B02001_001	B02001_002	N/A
Ethnic Minority	$\mathrm{EM}$	B03002_001	B03002_012	N/A
Foreign-Born	FB	$B05012\_001$	$B05012\_003$	N/A
Limited English Proficiency	$_{ m LEP}$	S1601_C01_001	S1601_C05_001	S1601_C06_001
Disabled	D	S1810_C01_001	S1810_C02_001	S1810_C03_001
Low-Income	$_{ m LI}$	S1701_C01_001	S1701_C01_042	N/A

While it's quicker to embed the names of the desired columns into the code, fields are explicitly spelled out in this script. This is a purposeful design choice. The user should check that the field names point to the correct API request with every IPD update. The best way to check the field names is to visit Census Developers (link) and select the corresponding API.

#### 1c. Year

The data download year.

```
ipd_year <- 2017
```

#### 1d. Functions

Load custom functions.

#### Override base and stats function defaults

A time-saver so that it's not required to call na.rm = TRUE every time these functions are called in other scripts.

```
min <- function(i, ..., na.rm = TRUE) {
   base::min(i, ..., na.rm = na.rm)
}
mean <- function(i, ..., na.rm = TRUE) {
   base::mean(i, ..., na.rm = na.rm)
}
sd <- function(i, ..., na.rm = TRUE) {
   stats::sd(i, ..., na.rm = na.rm)
}
max <- function(i, ..., na.rm = TRUE) {
   base::max(i, ..., na.rm = na.rm)
}</pre>
```

#### Create custom half-standard deviation breaks

For a given vector of numbers x and a number of bins i,  $st_dev_breaks$  computes the bin breaks starting at  $-0.5 \cdot stdev$  and  $0.5 \cdot stdev$ . For the purposes of IPD analysis, i = 5, and  $st_dev_breaks$  calculates the minimum,  $-1.5 \cdot stdev$ ,  $-0.5 \cdot stdev$ ,  $0.5 \cdot stdev$ ,  $1.5 \cdot stdev$ , and maximum values. These values are later used

to slice the vector into five bins. **Note** that all minima are coerced to equal zero and that if the first bin break is negative (this happens when our data have a large spread), then it is coerced to equal 0.001.

#### Move column or vector of columns to last position

The requested schema for IPD data export renames and places all relevant universes in the final columns of the dataset. move\_last moves a column or vector of columns to the last position in a tibble or data frame.

```
move_last <- function(df, last_col) {
  match(c(setdiff(names(df), last_col), names(df))
}</pre>
```

## Summarize data

The requested summary tables of IPD data call for more than base::summary exports. description tailors the exports from summarytools::descr to create summary tables with the requested fields.  $\frac{stdev}{2}$  is returned after stdev.

## Squared difference for variance replicates

```
sqdiff_fun <- function(v, e) (v - e) ^ 2
```

# 2. Variance replicate table download

This will feel out of order, but it's necessary — the racial minority indicator is created by summing up several subgroups in ACS Table B03002. This means that the MOE for the count has to be computed. While the ACS has issued guidance on computing the MOE by aggregating subgroups, in this instance, the large number of subgroups yields questionable MOEs. Variance replicate tables are used instead to compute a more accurate MOE. This single column is substituted in for the racial minority count MOE in Section 3.

## 2a. Download variance replicates from Census website

Download, unzip, and read variance replicate tables for Table B03002.

## 2b. Combine and format downloads

Combine the two states' variance replicate tables into one and subset for DVRPC region. Only extract the necessary subgroups.

# 3. Variance replicate table processing

## 3a. Compute racial minority count MOE

Add up the racial minority counts into a single count per census tract for the estimate and 80 variance replicates. Separate the resulting tibble into the estimates and the variance replicates.

```
num <- var_rep %>%
group_by(GEOID) %>%
summarize_if(is.numeric, funs(sum)) %>%
```

```
select(-GEOID)
estim <- num %>% select(estimate)
individual_replicate <- num %>% select(-estimate)
```

Compute the variance replicate for the count. GEOIDs are stored as id to be re-appended to the MOEs after they are calculated. Additional guidance on computing variance replicates is available at this (link).

```
id <- var_rep %>% select(GEOID) %>% distinct(.) %>% pull(.)
sqdiff <- mapply(sqdiff_fun, individual_replicate, estim)
sum_sqdiff <- rowSums(sqdiff)
variance <- 0.05 * sum_sqdiff
moe <- round(sqrt(variance) * 1.645, 0)</pre>
```

#### 3b. Save results

Save the racial minority MOE.

```
rm_moe <- cbind(id, moe) %>%
  as_tibble(.) %>%
  rename(GEOID = id, RM_CntMOE = moe)
```

Here are the first few lines of rm\_moe:

```
head(rm_moe)
```

## 4. ACS estimates download

#### 4a. Fields

Fields for downloads from the ACS API were discussed in Section 1b.

#### 4b. Download counts and universes from Census API

Download counts and percentages for each of IPD's nine indicators. Note that the download is for all census tracts in New Jersey and Pennsylvania (state = c(34,42)).

Input data for IPD comes from ACS Subject Tables, Detailed Tables, and Data Profiles. While one can request all the fields for Subject Tables in one batch, mixing requests for two different types (e.g. Subject Tables and Detailed Tables) will result in failure. For this reason, counts are downloaded in two batches: s\_counts for Subject Tables, and d\_counts for Detailed Tables.

Note two exceptions embedded in processing:

- 1. The API does not allow redundant downloads, so universes for Older Adults and Youth are duplicated after download.
- 2. This API call downloads variable B02001\_002 ("Estimate; Total: White alone") as the count, when the desired variable for Racial Minority is B02001\_001 B02001\_002. The subtraction is computed at the bottom of this code chunk.

```
s_counts <- get_acs(geography = "tract", state = c(34,42),</pre>
                    output = "wide", year = ipd_year,
                    variables = c(LI_U = low_income_universe,
                                   LI_C = low_income_count,
                                   F_U = female_universe,
                                   F_C = female_count,
                                   D_U = disabled_universe,
                                   D_C = disabled_count,
                                   # OA U = older adults universe, # Redundant download
                                   OA C = older adults count,
                                   LEP_U = limited_english_proficiency_universe,
                                   LEP C = limited english proficiency count)) %>%
  select(-NAME) %>%
  mutate(OA UE = F UE, OA UM = F UM)
d_counts <- get_acs(geography = "tract", state = c(34,42),</pre>
                    output = "wide", year = ipd_year,
                    variables = c(EM_U = ethnic_minority_universe,
                                   EM_C = ethnic_minority_count,
                                   \# Y_U = youth\_universe, \# Redundant download
                                   Y_C = youth_count,
                                   FB_U = foreign_born_universe,
                                   FB_C = foreign_born_count,
                                   RM_U = racial_minority_universe,
                                   RM_C = racial_minority_count)) %>%
  mutate(Y_UE = EM_UE, Y_UM = EM_UM, x = RM_UE - RM_CE) %>%
  select(-NAME, -RM_CE) %>%
  rename(RM CE = x)
```

## 4c. Download percentages from Census API

Download percentage tables that are available for four of IPD's nine indicators. We will compute percentages and their associated MOEs for the rest of the dataset later.

The API request limitations are similar to those above. Percentages are downloaded in two batches: s\_percs for Subject Tables, and dp\_percs for Data Profiles.

#### 4d. Combine and format downloads

Merge downloads into two separate data frames: dl\_counts for counts and universes, and dl\_percs for available percentages. Subset data frames for DVRPC's nine-county region.

```
dl_counts <- left_join(s_counts, d_counts) %>%
  filter(str_sub(GEOID, 1, 5) %in% keep_cty)
dl_percs <- left_join(s_percs, dp_percs) %>%
  filter(str_sub(GEOID, 1, 5) %in% keep_cty) %>%
  mutate_if(is.numeric, funs(. / 100))
```

#### Exception 4.1

Before computing percentages and percentage MOEs, import the count MOE for the Racial Minority variable computed from variance replicates. If rm\_moe.csv exists, then this chunk will substitute the correct count MOE in dl\_counts; if not, this chunk will do nothing.

```
if(TRUE %in% (list.files(here("outputs")) == "rm_moe.csv")){
  rm_moe <- read_csv(here("outputs", "rm_moe.csv")) %>%
    mutate_at(vars(GEOID), as.character)
  dl_counts <- dl_counts %>% left_join(., rm_moe) %>%
    select(-RM_CM) %>%
    rename(RM_CM = RM_CntMOE)
}
```

#### Exception 4.2

Half-standard deviations serve as the classification bins for IPD scores, and the overall number of tracts affects computed standard deviation values. Start by removing the 10 census tracts with zero population.

```
dl_counts <- dl_counts %>% filter(!(GEOID %in% slicer))
dl_percs <- dl_percs %>% filter(!(GEOID %in% slicer))
```

Here are the first few lines of dl\_counts and dl\_percs:

```
head(dl_counts)
```

```

```

# 5. Calculations

For all nine indicators, Section 4 computes:

- a. Percentages and their MOEs
- b. Percentile
- c. IPD Score and Classification
- d. Total IPD Score

Split dl\_counts into a list named comp for processing and sort column names for consistency. The name of the list, comp, is a nod to the "component parts" of dl\_counts. The structure of comp is similar to a four-tab Excel spreadsheet: for example, comp is the name of the .xlsx file, uni\_est is a tab for universe estimates, and uni\_est has nine columns and 1,379 rows, where the column is the IPD indicator and the row is the census tract observation.

The order of columns is important because processing is based on vector position. We want to make sure that the first column of every tab corresponds to the Disabled indicator, the second to Ethnic Minority, et cetera.

```
comp <- list()
comp$uni_est <- dl_counts %>% select(ends_with("UE")) %>% select(sort(current_vars()))
comp$uni_moe <- dl_counts %>% select(ends_with("UM")) %>% select(sort(current_vars()))
comp$count_est <- dl_counts %>% select(ends_with("CE")) %>% select(sort(current_vars()))
comp$count_moe <- dl_counts %>% select(ends_with("CM")) %>% select(sort(current_vars()))
```

## 5a. Percentages and percentage MOEs

#### Calculation

MOEs of the percentage values are obtained using the tidycensus function  $moe\_prop$ . This chunk mentions r and c several times: continuing the spreadsheet analogy, think of r as the row number and c as the column number for a given spreadsheet tab.

#### Result

pct and pct\_moe stores the percentages and associated MOEs for the nine indicator variables. Results are rounded to the tenths place.

```
pct <- as_tibble(pct_matrix) %>% mutate_all(round, 3)
names(pct) <- str_replace(names(comp$uni_est), "_UE", "_PctEst")
pct_moe <- as_tibble(pct_moe_matrix) %>% mutate_all(round, 3)
names(pct_moe) <- str_replace(names(comp$uni_est), "_UE", "_PctMOE")</pre>
```

#### Exception 5.2

```
If estimated percentage == 0 & MOE == 0, then make MOE = 0.1.

Matrix math: Only overwrite MOE where pct_matrix + pct_moe_matrix == 0.

overwrite_locations <- which(pct_matrix + pct_moe_matrix == 0, arr.ind = TRUE)
pct_moe[overwrite_locations] <- 0.1
```

#### Exception 5.3

Substitute percentages and associated MOEs when available from American FactFinder. This applies to the Older Adults, Female, Limited English Proficiency, and Disabled variables.

Here are the first few lines of pct and pct\_moe:

```
head(pct)
```

```

                                                                        0.031
## # ... with 2 more variables: RM_PctMOE <dbl>, Y_PctMOE <dbl>
```

## 5. Percentile

#### Calculation

Add percentages (an additional spreadsheet tab) to comp, making sure to first sort column names for consistency. Compute the empirical cumulative distribution function for each of the nine indicator variables.

```
comp$pct_est <- pct %>% select(sort(current_vars()))
percentile_matrix <- NULL
for (c in 1:length(comp$uni_est)){
  p <- unlist(comp$pct_est[,c])
  rank <- ecdf(p)(p)
  percentile_matrix <- cbind(percentile_matrix, rank)
}</pre>
```

#### Result

percentile stores the percentile for the nine indicator variables. Results are rounded to the hundredths place.

```
percentile <- as_tibble(percentile_matrix) %>% mutate_all(round, 2)
names(percentile) <- str_replace(names(comp$uni_est), "_UE", "_Pctile")</pre>
```

Here are the first few lines of percentile:

```
head(percentile)
```

```

                                                                          0.74
## # ... with 2 more variables: RM_Pctile <dbl>, Y_Pctile <dbl>
```

## 5c. Compute IPD score and classification

Each observation is assigned an IPD score for each indicator. The IPD score for an individual indicator can range from 0 to 4, which corresponds to the following:

IPD Score	IPD Classification	Standard Deviations
0	Well Below Average	x < -1.5stdev
1	Below Average	$-1.5stdev \le x < -0.5stdev$
2	Average	$-0.5stdev \le x < 0.5stdev$
3	Above Average	$0.5stdev \leq \mathbf{x} < 1.5stdev$
4	Well Above Average	$x \ge 1.5 stdev$

#### Calculation

```
score_matrix <- NULL</pre>
class_matrix <- NULL</pre>
for (c in 1:length(comp$uni_est)){
  p <- unlist(comp$pct_est[,c])</pre>
  breaks <- st_dev_breaks(p, 5, na.rm = TRUE)</pre>
  score <- case_when(p < breaks[2] ~ 0,</pre>
                       p >= breaks[2] & p < breaks[3] ~ 1,</pre>
                       p >= breaks[3] & p < breaks[4] ~ 2,</pre>
                       p >= breaks[4] & p < breaks[5] ~ 3,</pre>
                       p >= breaks[5] ~ 4)
  class <- case_when(score == 0 ~ "Well Below Average",</pre>
                       score == 1 ~ "Below Average",
                       score == 2 ~ "Average",
                       score == 3 ~ "Above Average",
                       score == 4 ~ "Well Above Average")
  score_matrix <- cbind(score_matrix, score)</pre>
  class_matrix <- cbind(class_matrix, class)</pre>
}
```

#### Result

head(class)

score and class store the IPD scores and associated descriptions for the nine indicator variables.

```
score <- as_tibble(score_matrix)
names(score) <- str_replace(names(comp$uni_est), "_UE", "_Score")
class <- as_tibble(class_matrix)
names(class) <- str_replace(names(comp$uni_est), "_UE", "_Class")</pre>
```

Here are the first few lines of score and class:

```
head(score)
```

```

## # ... with 2 more variables: Y_Score <dbl>, IPD_Score <dbl>
```

# 6. Cleaning

There is a specific output format for ipd.csv, including column names, column order, flags for missing data, and census tracts with insufficient data. This section ensures conformity with the output formatting.

Transform percentage estimates and their MOEs into values ranging from 0 to 100 instead of 0 to 1 and round to the tenths place.

```
pct <- pct %>%
  mutate_all(funs(. * 100)) %>%
  mutate_all(round, 1)
pct_moe <- pct_moe %>%
  mutate_all(funs(. * 100)) %>%
  mutate_all(funs(. * 100)) %>%
```

Merge the percentage estimates, their MOEs, rank (percentile), score, and class tibbles into a single data frame called ipd.

```
ipd <- bind_cols(dl_counts, pct) %>%
bind_cols(., pct_moe) %>%
bind_cols(., percentile) %>%
bind_cols(., score) %>%
bind_cols(., class)
```

Rename columns.

Reorder columns, with GEOID first, the following variables in alphabetical order, and the total IPD score and universes at the end.

Tack unwanted columns back onto the final dataset.

```
slicer <- enframe(slicer, name = NULL, value = "GEOID")
ipd <- plyr::rbind.fill(ipd, slicer)</pre>
```

Replace NA values with NoData if character and -99999 if numeric.

```
ipd <- ipd %>% mutate_if(is.character, funs(ifelse(is.na(.), "NoData", .))) %>%
    mutate_if(is.numeric, funs(ifelse(is.na(.), -99999, .)))
```

# 6. Summary Tables

```
# Replace -99999 with NA for our purposes
ipd_summary <- ipd</pre>
ipd_summary[ipd_summary == -99999] <- NA</pre>
